

ADR Identifications Basics

Patient: 45 years old female.

Presenting Symptoms: Skin rash, generalized itching, nausea, and dizziness.

Medication History:

Amoxicillin (initiated 5 days prior).

Paracetamol (taken as needed).

Timeline Assessment: Symptoms began following 5 days of continuous Amoxicillin therapy.

Suspected Agent: Amoxicillin (Beta-lactam antibiotic).

Mechanism of ADR: Hypersensitivity reaction (Type I immediate IgE-mediated or Type IV delayed cell-mediated immune response), which frequently presents as cutaneous maculopapular rash and pruritus.

Differential Assessment: Paracetamol taken sporadically is far less likely to trigger a delayed cutaneous reaction compared to a 5-day course of a beta-lactam antibiotic.

Conclusion: So, the adverse reaction is drug-related, directly attributed to Amoxicillin.
